1 Introduction

I used to create several documents using L^AT_EX (or plain T_EX but T_EX is quite cumbersome to write—especially when working with very complex tables or inserting images). Its markdown-like syntax is also not comfortable to use. For example, here is a simple L^AT_EX document:

```
1 % coprime is my custom class. See https://github.com/e0328eric/coprime.
2 \documentclass[tikz, geometry]{coprime}
3
4 \settitle{My First Document}{Sungbae Jeong}{}
5 \setgeometry{a4paper, margin = 2.5cm}
6
7 \begin{document}
8 \section{Foo}
9 Hello, World!
10 \begin{figure}[ht]
11   \centering
12   \begin{tikzpicture}
13     \draw (0,0) -- (1,1);
14   \end{tikzpicture}

```

```

15 \end{figure}
16
17 The code above is a figure using TikZ.
18
19 \end{document}

```

What annoys me most when using it is the ‘\begin’ and ‘\end’ blocks. Is there a way to write something much simpler? This question led me to start this project. Currently, the following code is generated into the $\text{\LaTeX}$ code above (except comments) using vesti:

```

1 % coprime is my custom class. See https://github.com/e0328eric/coprime.
2 \docclass coprime (tikz, geometry)
3
4 \settitle{My First Document}{Sungbae Jeong}{}
5 \setgeometry{a4paper, margin = 2.5cm}
6
7 \startdoc
8
9 \section{Foo}
10 Hello, World!
11 \useenv figure [ht] {
12     \centering
13     \useenv tikzpicture {
14         \draw (0,0) -- (1,1);
15     }
16 }
17
18 The code above is a figure using TikZ.

```

Everywhere in this paper, the symbol $\square$ denotes a “space” when one use Vesti.

2 Structure of Vesti File

Vesti is similar as $\text{\LaTeX}$. Its structure consists with two parts: **preamble** and **main**. Preamble is the place where $\text{\LaTeX}$ documentclass, packages, and several settings are located. Main body is where actual documentation is located. Below figure is the simple Vesti documentation.

```

1 \docclass article (10pt)
2 \importpkg {
3     geometry (a4paper, margin=2.2cm)
4 }
5 \startdoc
6 Hello, Vesti!

```

We will see later, but the very difference with $\text{\LaTeX}$ is that Vesti has its own keywords (keywords are colored with purple). It makes the code readable and it is easier and faster to write the document. The keyword `startdoc` splits the preamble and the main part of the documentation similar with

`\begin{document}` in $\text{\LaTeX}$. However, Vesti does not have the analogous part of `\end{document}`, because almost every $\text{\LaTeX}$ document (99.999% I’m sure) does not have any code below `\end{document}`. For this reason, Vesti automatically ends document when EOF (End Of File) is found.

3 Keywords

Followings are reserved as keywords. In this document, every Vesti keyword has the form like **this**.

<code>beginv</code>	<code>compty</code>	<code>cpfile</code>	<code>defenv</code>
<code>defun</code>	<code>docclass</code>	<code>endenv</code>	<code>importmod</code>
<code>importpkg</code>	<code>importves</code>	<code>startdoc</code>	<code>useenv</code>

Table 1: Keywords in Vesti

3.1 `docclass` keyword

Keyword `docclass` is an analogous of `\documentclass` in $\text{\LaTeX}$. If `docclass` is in the main paragraph, it acts just a normal word. In other words, `docclass` activates only in the preamble. The syntax of `docclass` is following:

`docclass` $\square$ `<class name>` $\square$ `(<arguments>)`

Here, arguments are separated by commas and embraced by `()`. Here are some examples.

- `docclass` $\square$ `article`
- `docclass` $\square$ `article` $\square$ `(10pt)`
- `docclass` $\square$ `article` $\square$ `(10pt, \square twocols)`
- `docclass` $\square$ `article` $\square$ `(10pt,twocols)`

3.2 `importpkg` keywords

Keyword `importpkg` is an analogous of `\usepackage` in $\text{\LaTeX}$. If `importpkg` is in the main paragraph, it acts just a normal word. In other words, `importpkg` activates only in the preamble.

`importpkg` has two different syntax. First one is same as `docclass`.

`importpkg` $\square$ `<pkg-name>` $\square$ `(arguments)`

Here, arguments are separated by commas and embraced by `()`. In the practical case, one should include several packages with options. `importpkg` also supports such case. We will look at an example instead of giving rigorous grammar.

```

1 importpkg {
2   amsmath, amssymb, amsthm,
3   geometry (a4paper, margin=2.2cm),
4 }

```

As one can see, inside of `{}`, several packages can be used together with their options.

3.3 `startdoc` keyword

Keyword `startdoc` tells to Vesti that the main document starts. In the main document, you can also write `startdoc` in the main document. In that case, `startdoc` does nothing.

3.4 `useenv` keyword

As the name implies, keyword `useenv` is an analogous of `\begin{...}` and `\end{...}` pair in $\text{\LaTeX}$. The simplest `useenv` is like this.

`useenv` `center` {
Hello, World! or `useenv` `center` { Hello, World! }
}

As you can see, `useenv center` is the part of `\begin{center}`, and the single `}` is the part of `\end{center}`. Since Vesti knows their pair, one can write a code with several environment, and each pair is properly matched. For instance, above example is written in Vesti like follows. Here, `\useenv` just prints `useenv` in that style.

```

1 useenv figure [ht] {
2   \centering
3   useenv tikzpicture {
4     useenv scope {
5       \path (0,0) node {\vbox{
6         %#\hbox{\tt\useenv center \{}
7         %#\hbox{\tt\obeyspaces Hello, World!}
8         %#\hbox{\tt\obeyspaces\}}
9       }
10    }
11    \path (2.3,0) node {or};
12    useenv scope [shift={(6,0)}] {
13      \path (0,0) node {\tt\useenv center \{ Hello, World! \}};
14    }
15  }
16 }

```

Full syntax about **useenv** is the following.

useenv $\sqcup$ <environment name> $\sqcup$ <argument>* $\sqcup$ { <body> }

where “*” means that the number of <argument> is zero or at least one, and

$$\text{<argument>} = \begin{cases} (\text{<argument>}) & \text{mandatory arguments} \\ [\text{<argument>}] & \text{optional arguments} \end{cases}$$

For instance, below one is a valid Vesti code (environment **foo** is undefined in general). As one can see, spaces cannot exist in between <argument>s.

```

1 useenv foo (asd)(fff)[\ames and \awdsa](askws)[\rrsaa] {
2   foobar
3 }

```

3.5 **beginv** and **endenv** keywords

As the name implies, both keywords **beginv** and **endenv** are analogous of **\begin{...}** and **\end{...}** pair in $\text{\LaTeX}$, respectively. Thus below code

```

1 beginv center
2   asdsad
3 endenv

```

is exactly same as

```

1 useenv center {
2   asdsad
3 }

```

Then why we need **beginv** and **endenv** if we already have **useenv**? The only reason which both **beginv** and **endenv** exist is defining new environment. For instance, one defines a new environment like following.

```

1 defenv foo {beginv minipage(\textwidth)}{endenv}

```

3.6 **defun** keyword

defun is the keyword which makes a $\text{\LaTeX}$ function. Internally, it uses **xparse** package which is automatically included from modern $\text{\LaTeX}$ 2 ϵ kernel. The grammar of **defun** is the following.

defun $\sqcup$ [<attr>]? $\sqcup$ <command-name> $\sqcup$ (<param-spec>)? $\sqcup$ {<implementation>}

Here, `~?` means that this is an optional.

First, let us see some examples for `defun`, and then explain the meaning of each fields.

```
1 \defun foo {Hello, World!}
```

4 Builtin

Vesti also has its own builtin functions, which are prefixed with `#`. One might wonder what distinguishes builtins from keywords. In fact, from the compiler’s internal perspective, there is no real difference. However, in actual language usage, constantly typing the prefix can be somewhat tedious, especially for functions that are commonly used.

From the perspective of language design sometimes desirable to use names that can not be reserved as keywords. For example, Vesti provides a built-in function `#label`, which will be explained later. Since Vesti is a typewriting-oriented language, the word “label” is often used in its ordinary sense rather than in its special semantic meaning within the language.

Followings are reserved as builtin functions.

<code>#at_off</code>	<code>#at_on</code>	<code>#chardef</code>	<code>#def</code>	<code>#enum</code>
<code>#enum_counter</code>	<code>#eq</code>	<code>#get_filepath</code>	<code>#include</code>	<code>#label</code>
<code>#ltx3_off</code>	<code>#ltx3_on</code>	<code>#mathchardef</code>	<code>#mathmode</code>	<code>#noltx3</code>
<code>#picture</code>	<code>#raw_tex</code>	<code>#showfont</code>	<code>#textmode</code>	<code>#undef</code>

Table 2: Builtins in Vesti

Since `fancyvrb` does not allow verbatim-like commands inside of `Verbatim` environment, builtins are not colored in example codes.

4.1 `#label` builtin

For the compiling issue, if one label some environment, one should write like follows using $\text{\LaTeX}$ function `\label`.

```
1 useenv theorem { \label{eq:1}
2   1 + 1 = 2.
3 }
```

However, such code is not natural. Thus `#label` comes into the place. One can label environments using `#label` builtin like this.

```
1 #label(eq:1) useenv theorem {
2   1 + 1 = 2.
3 }
```

One can also write like the following, which I personally prefer.

```
1 #label(eq:1)
2 useenv theorem {
3   1 + 1 = 2.
4 }
```

4.2 `#eq` builtin

`#eq` is a abbreviation of ‘`useenv equation`’. Actually, below codes are same.

```
1 #label(eq:1)
2 useenv equation {
3   \sum_{n=1}^{\infty} {1//n^2} = {\pi^2//6}.
4 }
```

```

1 #eq(eq:1) {
2   \sum_{n=1}^{\infty} {1//n^2} = {\pi^2//6}.
3 }

```

Since Vesti is used in the mathematical documents mainly, small syntactic sugar is needed, so Vesti introduces `#eq` builtin.

4.3 `#chardef` builtin

`#chardef` defines a text token using the unicode codepoint. Here is the grammar of `#chardef` builtin.

$$\text{\#chardef} \quad \langle \text{unicode-codepoint} \rangle \quad \langle \text{function} \rangle$$

Here, $\langle \text{unicode-codepoint} \rangle$ must be hexadecimal.

4.4 `#mathchardef` builtin

`#mathchardef` defines a math token using the unicode codepoint. Here is the grammar of `#mathchardef` builtin.

$$\text{\#mathchardef} \quad \langle \text{kind} \rangle \quad \langle \text{font-num} \rangle \quad \langle \text{unicode-codepoint} \rangle \quad \langle \text{function} \rangle$$

Here, $\langle \text{unicode-codepoint} \rangle$ must be hexadecimal. Before explaining each parameter, introduce some examples.

- `#mathchardef .opening 0 29d8 \lfoo`
- `#mathchardef .ordinary 0 2202 \diff`

4.5 `#enum` and `#enum_counter` builtins

`#enum` builtin is just an enumerate environment with minimal support of `enumitem` feature. For example,

```

1 #enum {
2   \item aaa
3   \item bbb
4   \item ccc
5 }

```

prints

1. aaa
2. bbb
3. ccc

`#enum` also can be nested like follows.

```

1 #enum {
2   \item aaa
3   \item #enum {
4     \item bbb
5     \item ccc
6   }
7   \item ddd
8 }

```

It prints

1. aaa
2. (a) bbb

(b) ccc

3. ddd

To customize a format of `\item` like `enumitem`, one can write like the following:

```
1 #enum (\Roman*. ) {  
2   \item aaa  
3   \item #enum ({\roman*}**) {  
4     \item bbb  
5     \item ccc  
6   }  
7   \item ddd  
8 }
```

I. aaa

II. i* bbb
 ii* ccc

III. ddd

As one can see, `#enum` changes the format with inside of `()`. In Vesti, single `*` changes into `{<enum count>}` (including braces), and consecutive `**` changes into single `*` character. Thus, `\Roman*.` changes into `\Roman{enumi}.` and `{\roman*}**` changes into `{\roman{enumii}}*` (because this part is inside of another `#enum`).

Beware that by the parting mechanism, `\roman***` changes into `\roman*{<enum count>}`, and `\roman{*}**` into `\roman*{<enum count>}`, which are invalid arguments for `\roman` L^AT_EX internal command.

`#enum_counter` builtin is a helper to get the name of the current enum counter. For example, if one wants to start a second enum from 3, one can write

```
1 #enum {  
2   \item aaa  
3   \item #enum {  
4     \setcounter{#enum_counter}{2}  
5     \item bbb  
6     \item ccc  
7   }  
8   \item ddd  
9 }
```

and it prints

1. aaa
2. (c) bbb
 (d) ccc
3. ddd

4.6 `#get_filepath` builtin

Because of the Vesti internal, if one includes picture by using `\includegraphics` for instance, providing the raw path cause an error from L^AT_EX with “file not found”. `#get_filepath` builtin adjust raw file path into the new relative one which L^AT_EX knows. Here is the example code.

```
1 \includegraphics{#get_filepath(./foo.png)}
```

Internally, `#get_filepath` changes file path into the relative one with respect to `.vesti-dummy`. For example, if `foo.png`, `foo.ves` and `.vesti-dummy` are located in the root directory, then inside of `foo.ves`, `#get_filepath(./foo.png)` will be changed into `../foo.png` because for `.vesti-dummy`, `foo.png` is located outside of it.

4.7 #at_on and #at_off builtins

Both builtins are same as L^AT_EX functions `\makeatletter` and `\makeatother` plus changes Vesti lexer such that `@` character is also can be a L^AT_EX function name. For instance, without using `#at_on` command, below code does not compiles.

```
1 defun @foo (#1) {Hello, #1!}
```

This is because `defun` expects a valid L^AT_EX function name but the character `@` is not a valid one except after the `\makeatletter` function. Since `defun` is a Vesti grammar, there is no way to tell Vesti that `@` is a right one although one uses `\makeatletter`. By using `#at_on`, below code then compiles.

```
1 #at_on
2 defun @foo (#1) {Hello, #1!}
3 #at_off
```

One can not using `#at_off`, but I strongly recommend to match pairs.

4.8 #ltx3_on and #ltx3_off builtins

Those builtins are similar with `#at_on` and `#at_off` pairs but for L^AT_EX3.

4.9 #textmode and #mathmode builtins

Internally, vesti tracks so called `text` mode and `math` mode. In the math mode, for instance, the token `->` is changed into `→` inside of the math mode. The idea is that Vesti changes `->` into `\to`, and so on. But when defining some function using `defun`, for example, one might want to define

```
1 useenv foo {-><-}
```

so that `$(foo)` makes `→←`, one should change the mode. Here, `#mathmode` comes into the place. One should write instead that

```
1 useenv foo {#mathmode{-><-}}
```

5 Lua API

Vesti uses Lua in both building script and inline inside of Vesti code. Below are functions which are baked in Vesti compiler.

compile	download	getCurrentDir	getEngineType
getModule	joinpath	mkdir	parse
ping	print	setCurrentDir	unzip
vestiDummyDir			

Table 3: Lua builtin functions in Vesti

6 Source Code of This Document

Below code was generated by inline lua.

```
1 docclass article (10pt)
2 importpkg {
3     geometry (a4paper, margin = 2.2cm),
4     xcolor,
5     tikz,
6     fancyvrb,
7     amsmath,
8 }

131 }
132 +keyword|startdoc@
133 Hello, Vesti!
134 -%}
135
136 We will see later, but the very difference with \LaTeX\ is that Vesti has its
137 own keywords (keywords are colored with purple). It makes the code readable and
138 it is easier and faster to write the document. The keyword startdoc splits
139 the preamble and the main part of the documentation similar with
140
141 -- Don't ask why I chose Q for catcode 0.
142 %#{\tt\catcode`Q=0 Qcatcode`\\=12 \beginQ{documentQ}} in \LaTeX.
143 However, Vesti does not have the analogous part of
144 %#{\tt\catcode`Q=0 Qcatcode`\\=12 \endQ{documentQ}},
145 because almost every \LaTeX\ document (99.999\% I'm sure) does not have any code
146 below %#{\tt\catcode`Q=0 Qcatcode`\\=12 \endQ{documentQ}}.
147 For this reason, Vesti automatically ends document when EOF (End Of File) is
148 found.
149
150 \section{Keywords}
151 Followings are reserved as keywords. In this document, every Vesti keyword has
152 the form like \keyword{this}.
153 useenv table [ht] {
154     \centering
155     #::
156     local content = read_all("../src/lexer/Token.zig")
157
158     -- Lua's built-in patterns don't support lookahead.
159     -- We capture both the keyword and the TokenType, then filter out 'deprecated'.
160     -- Pattern breakdown:
161     --   %.{          => matches ".{"
162     --   %s*"([~"]+)" => a quoted string -> capture 1
163     --   %s*,%s*TokenType%.([%w_]+) => TokenType.<Name> -> capture 2
164     local pat = "%.{%s*"([~"]+)"%s*,%s*TokenType%.([%w_]+)"
165
166     local keywords = {}
167     for name, tok in content:gmatch(pat) do
168         if tok ~= "deprecated" then
169             keywords[#!keywords + 1] = name
170         end
171     end
172
173     table.sort(keywords)
174
175     vesti.print([[begin{tabular}{cccc}]]
176

```

```

177   for i, kw in ipairs(keywords) do
178       local cell = string.format("\\keyword{%s}", kw)
179       if (i % 4) == 0 then
180           vesti.print(cell .. [[\\]])
181       else
182           vesti.print(cell .. "&")
183       end
184   end
185
186   vesti.print([[\\end{tabular}]]))
187   ::#[readAll]
188   \\caption{Keywords in Vesti}
189 }
190
191 \\subsection{\\keyword{docclass} keyword}
192 Keyword \\keyword{docclass} is an analogous of \\verb|\\documentclass| in \\LaTeX.
193 If \\keyword{docclass} is in the main paragraph, it acts just a normal word.
194 In other words, \\keyword{docclass} actives only in the preamble.
195 The syntax of \\keyword{docclass} is following:
196
197 useenv center {
198     \\keyword{docclass}\\ob<class name>\\ob{\\tt{<arguments>}{\\tt}}
199 }
200 Here, arguments are separated by commas and embraced by {\\tt ()}. Here are some
201 examples.
202
203 \\goodbreak
204 useenv itemize {
205     \\item \\keyword{docclass}\\ob{\\tt article}
206     \\item \\keyword{docclass}\\ob{\\tt article\\ob(10pt)}
207     \\item \\keyword{docclass}\\ob{\\tt article\\ob(10pt,\\ob twocols)}
208     \\item \\keyword{docclass}\\ob{\\tt article\\ob(10pt,twocols)}
209 }
210
211 \\subsection{\\keyword{importpkg} keywords}
212 Keyword \\keyword{importpkg} is an analogous of \\verb|\\usepackage| in \\LaTeX.
213 If \\keyword{importpkg} is in the main paragraph, it acts just a normal word.
214 In other words, \\keyword{importpkg} actives only in the preamble.
215
216 importpkg has two different syntax. First one is same as docclass.
217 useenv center {
218     \\keyword{importpkg}\\ob<pkg-name>\\ob{\\tt{arguments}{\\tt}}
219 }
220 Here, arguments are separated by commas and embraced by {\\tt ()}.
221 In the practical case, one should include several packages with options.
222 importpkg also supports such case. We will look at an example instead of
223 giving rigorous grammar.
224 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
225 +keyword|importpkg@ {
226     amsmath, amssymb, amsthm,
227     geometry (a4paper, margin=2.2cm),
228 }
229 -%}
230
231 \\noindent As one can see, inside of \\verb|{}|, several packages can be used
232 together with thier options.
233
234 \\subsection{\\keyword{startdoc} keyword}
235 Keyword \\keyword{startdoc} tells to Vesti that the main document starts. In the
236 main document, you can also write \\keyword{startdoc} in the main document. In

```

```

237 that case, \keyword{startdoc} does nothing.
238
239 \subsection{\useenv keyword}
240 As the name implies, keyword \useenv is an analogous of \verb|\begin{...}| and
241 \verb|\end{...}| pair in \LaTeX.
242 The simplest \useenv is like this.
243
244 useenv figure [ht] {
245     \centering
246     useenv tikzpicture {
247         useenv scope {
248             \path (0,0) node {\vbox{
249                 %#\hbox{\tt\useenv center \{ }
250                 %#\hbox{\tt\obeyspaces Hello, World!}
251                 %#\hbox{\tt\obeyspaces\}}
252             }};
253         }
254         \path (2.3,0) node {or};
255         useenv scope [shift={(6,0)}]{
256             \path (0,0) node {\tt\useenv center \{ Hello, World! \}};
257         }
258     }
259 }
260
261 As you can see, {\tt\useenv center} is the part of \verb|\begin{center}|, and
262 the single {\tt\}} is the part of \verb|\end{center}|. Since Vesti knows their
263 pair, one can write a code with several environment, and each pair is properly
264 matched. For instance, above example is written in Vesti like follows. Here,
265 \verb|\useenv| just prints \useenv in that style.
266
267 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
268 |+color|purple@useenv@ figure [ht] {
269     \centering
270     |+color|purple@useenv@ tikzpicture {
271         |+color|purple@useenv@ scope {
272             \path (0,0) node {\vbox{
273                 |+color|blue@%#\hbox{\tt\useenv center \{ }
274                 |+color|blue@%#\hbox{\tt\obeyspaces Hello, World!}
275                 |+color|blue@%#\hbox{\tt\obeyspaces\}}
276             }};
277         }
278         \path (2.3,0) node {or};
279         |+color|purple@useenv@ scope [shift={(6,0)}] {
280             \path (0,0) node {\tt\useenv center \{ Hello, World! \}};
281         }
282     }
283 }
284 -%}
285
286 Full syntax about \useenv is the following.
287 useenv center {
288     \useenv\ob<environment name>\ob<argument>*\ob{\tt\{ } <body> {\tt\}}
289 }
290 where `*' means that the number of <argument> is zero or at least one, and
291 $$
292     "<argument>" = useenv cases {
293         "<argument>" & "mandatory arguments" \cr
294         "[<argument>]" & "optional arguments" \cr
295     }
296 $$

```

```

297 For instance, below one is a valid Vesti code (environment {\tt foo} is
298 undefined in general). As one can see, spaces cannot exist in between <argument>s.
299 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
300 |+color|purple@useenv@ foo (asd)(fff)[\ames and \awdsa](askws)[\rrsaa] {
301     foobar
302 }
303 -%}
304
305 #def #begenv {#::begenv(false,true)::#*}
306 #def #begenv_arg {#::begenv(#1,#2)::#*}
307 #def #endenv {#::endenv(false,true)::#*}
308 #def #endenv_arg {#::endenv(#1,#2)::#*}
309
310 \subsection{#begenv and #endenv keywords}
311 As the name implies, both keywords #begenv and #endenv are
312 analogous of \verb|\begin{...}| and \verb|\end{...}| pair in \LaTeX,
313 respectively. Thus below code
314 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
315 |+color|purple@begenv@ center
316     asdsad
317 |+color|purple@endenv@
318 -%}
319 is exactly same as
320 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
321 +keyword|useenv@ center {
322     asdsad
323 }
324 -%}
325 Then why we need #begenv and #endenv if we already have \useenv*?
326 The only reason which both #begenv and #endenv exist is
327 defining new environment. For instance, one defines a new environment like
328 following.
329 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@] {
330 %#+keyword|defenv@ foo { |+color|purple@begenv@ minipage(\textwidth)}{ |+color|purple@endenv@}
331 }
332
333 \subsection{\defun keyword}
334 \defun is the keyword which makes a \LaTeX\ function. Internally, it uses {\tt
335 xparse} package which is automatically included from modern \LaTeX$2\epsilon$
336 kernel. The grammar of \defun is the following.
337
338 begenv center
339     \defun\ob[<attr>]?\ob<command-name>\ob(<param-spec>)?\ob\{<implementation>\}
340 endenv
341 Here, {\tt`?`} means that this is an optional.
342
343 First, let us see some examples for \defun*, and then explain the meaning of
344 each fields.
345
346 #::
347 local examples = {
348     "\defun foo {Hello, World!}"
349 }
350
351 for _, example in ipairs(examples) do
352     vesti.print(vesti.parse(
353         "begenv! Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]"
354     ))
355     vesti.print(example)
356     vesti.print(vesti.parse("endenv! Verbatim"))

```

```

357 end
358 ::#
359
360 \section{Builtins}
361 Vesti also has its own builtin functions, which are prefixed with \#.
362 One might wonder what distinguishes builtins from keywords. In fact, from the
363 compiler's internal perspective, there is no real difference. However, in actual
364 language usage, constantly typing the prefix can be somewhat tedious, especially
365 for functions that are commonly used.
366
367 From the perspective of language design --particularly in Vesti-- it is
368 sometimes desirable to use names that can not be reserved as keywords. For example,
369 Vesti provides a built-in function \builtin|label|, which will be explained
370 later. Since Vesti is a typewriting-oriented language, the word \lq\lq
371 label\rq\rq\ is often used in its ordinary sense rather than in its special
372 semantic meaning within the language.
373
374 Followings are reserved as builtin functions.
375
376 useenv table [ht] {
377     \centering
378     #::
379     local content = read_all("../src/lexer/Token.zig")
380
381     -- match .{ "here" }
382     local pat = "%.{%s*\"([^\"]+)\">%s*%}"
383
384     local builtins = {}
385     for name, tok in content:gmatch(pat) do
386         builtins[#!builtins + 1] = name
387     end
388     table.sort(builtins)
389
390     vesti.print([[ \begin{tabular}{ccccc} ]])
391
392     for i, kw in ipairs(builtins) do
393         local cell = string.format("\\builtin@%s@", kw)
394         if (i % 5) == 0 then
395             vesti.print(cell .. [[ \\ ]])
396         else
397             vesti.print(cell .. "&")
398         end
399     end
400
401     vesti.print([[ \\end{tabular} ]])
402     ::#[readAll]
403     \caption{Builtins in Vesti}
404 }
405 Since {\tt fancyvrb} does not allow verbatim-like commands inside of
406 {\tt Verbatim} environment, builtins are not colored in example codes.
407
408 \subsection{\builtin|label| builtin}
409 For the compiling issue, if one label some environment, one should write like
410 follows using \LaTeX\ function \verb|\label|.
411 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=&|@]{%-
412 &keyword|useenv@ theorem { \label{eq:1}
413     1 + 1 = 2.
414 }
415 -%}
416

```

```

417 However, such code is not natural. Thus \builtin|label| comes into the place.
418 One can label environments using \builtin|label| builtin like this.
419 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=&|@]{%-
420 #label(eq:1) &keyword|useenv@ theorem {
421     1 + 1 = 2.
422 }
423 -%}
424 One can also write like the following, which I personally prefer.
425 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=&|@]{%-
426 #label(eq:1)
427 &keyword|useenv@ theorem {
428     1 + 1 = 2.
429 }
430 -%}
431
432 \subsection{\builtin|eq| builtin}
433 \builtin|eq| is a abbreviation of \lq\keyword{%-useenv-%} equation\rq.
434 Actually, below codes are same.
435
436 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
437 #label(eq:1)
438 +keyword|useenv@ equation {
439     \sum_{n=1}^{\infty} {1//n^2} = {\pi^2//6}.
440 }
441 -%}
442 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
443 #eq(eq:1) {
444     \sum_{n=1}^{\infty} {1//n^2} = {\pi^2//6}.
445 }
446 -%}
447 Since Vesti is used in the mathematical documents mainly, small syntactic suger
448 is needed, so Vesti introduce \builtin|eq| builtin.
449
450 \subsection{\builtin|chardef| builtin}
451 \builtin|chardef| defines a text token using the unicode codepoint.
452 Here is the grammar of \builtin|chardef| builtin.
453 useenv center {
454     \builtin|chardef|\ob<unicode-codepoint>\ob<function>
455 }
456 Here, <unicode-codepoint> must be hexadecimal.
457
458 \subsection{\builtin|mathchardef| builtin}
459 \builtin|mathchardef| defines a math token using the unicode codepoint.
460 Here is the grammar of \builtin|mathchardef| builtin.
461 useenv center {
462     \builtin|mathchardef|\ob<kind>\ob<font-num>\ob<unicode-codepoint>\ob<function>
463 }
464 Here, <unicode-codepoint> must be hexadecimal.
465 Before explaining each parameter, introduce some examples.
466 useenv itemize {
467     \item \builtin|mathchardef|\ob.opening\ob0\ob29d8\ob\verb|\lfooo|
468     \item \builtin|mathchardef|\ob.ordinary\ob0\ob2202\ob\verb|\diff|
469 }
470
471 \subsection{\builtin|enum| and \builtin|enum_counter| builtins}
472 \builtin|enum| builtin is just an enumerate environment with minimal support of
473 {\tt enumitem} feature. For example,
474 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
475 #enum {
476     \item aaa

```

```

477     \item bbb
478     \item ccc
479 }
480 -%}
481 prints
482 #enum {
483     \item aaa
484     \item bbb
485     \item ccc
486 }
487 \builtin|enum| also can be nested like follows.
488 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
489 #enum {
490     \item aaa
491     \item #enum {
492         \item bbb
493         \item ccc
494     }
495     \item ddd
496 }
497 -%}
498 It prints
499 #enum {
500     \item aaa
501     \item #enum {
502         \item bbb
503         \item ccc
504     }
505     \item ddd
506 }
507 To customize a format of \verb|\item| like {\tt enumitem}, one can
508 write like the following:
509 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
510 #enum (\Roman*. ) {
511     \item aaa
512     \item #enum ({\roman*}**) {
513         \item bbb
514         \item ccc
515     }
516     \item ddd
517 }
518 -%}
519 #enum (\Roman*. ) {
520     \item aaa
521     \item #enum ({\roman*}**) {
522         \item bbb
523         \item ccc
524     }
525     \item ddd
526 }
527 As one can see, \builtin|enum| changes the format with inside of {\tt()}.
528 In Vesti, single {\tt *} changes into {\tt \{<enum count>\}} (including braces),
529 and consecutive {\tt **} changes into single {\tt *} character.
530 Thus, \verb|\Roman*.| changes into \verb|\Roman{enumi}.| and \verb|{\roman*}**|
531 changes into \verb|{\roman{enumii}}*| (because this part is inside of another
532 \builtin|enum|).
533
534 Beware that by the parting mechanism, \verb|\roman***| changes into
535 \verb|\roman*<enum count>|, and \verb|\roman{*}**| into \verb|\roman{\<enum count>}*|,
536 which are invalid arguments for \verb|\roman| \LaTeX\ internal command.

```

```

537
538 \builtin|enum_counter| builtin is a helper to get the name of the current enum
539 counter. For example, if one wants to start a second enum from 3, one can write
540 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
541 #enum {
542     \item aaa
543     \item #enum {
544         \setcounter{#enum_counter}{2}
545         \item bbb
546         \item ccc
547     }
548     \item ddd
549 }
550 -%}
551 and it prints
552 #enum {
553     \item aaa
554     \item #enum {
555         \setcounter{#enum_counter}{2}
556         \item bbb
557         \item ccc
558     }
559     \item ddd
560 }
561
562 \subsection{\builtin|get_filepath| builtin}
563 Because of the Vesti internal, if one includes picture by using
564 \verb|\includegraphics| for instance, providing the raw path cause an error from
565 \LaTeX\ with \lq\lq file not found\rq\rq. \builtin|get_filepath| builtin adjust
566 raw file path into the new relative one which \LaTeX\ knows. Here is the example
567 code.
568 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@] {
569 %#\includegraphics{#get_filepath(./foo.png)}
570 }
571 Internally, \builtin|get_filepath| changes file path into the relative one with
572 respect to {\tt.vesti-dummy}. For example, if {\tt foo.png}, {\tt foo.ves}
573 and {\tt.vesti-dummy} are located in the root directory, then inside of {\tt
574 foo.ves}, \builtin|get_filepath|{\tt(./foo.png)} will changed into
575 {\tt../foo.png} because for {\tt.vesti-dummy}, {\tt foo.png} is located outside
576 of it.
577
578 \subsection{\builtin|at_on| and \builtin|at_off| builtins}
579 Both builtins are same as \LaTeX\ functions \verb|\makeatletter| and
580 \verb|\makeatother| plus changes Vesti lexer such that \verb|@| character is
581 also can be a \LaTeX\ function name. For instance, without using \builtin|at_on|
582 command, below code does not compiles.
583 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|&] {
584 %#+keyword|defun& @foo (#1) {Hello, #1!}
585 }
586 This is because \keyword{% -defun-%} expects a valid \LaTeX\ function name but
587 the character \verb|@| is not a valid one except after the \verb|\makeatletter|
588 function. Since \keyword{% -defun-%} is a Vesti grammar, there is no way to tell
589 Vesti that \verb|@| is a right one although one uses \verb|\makeatletter|.
590 By using \builtin|at_on|, below code then compiles.
591 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|&]{%-
592 #at_on
593 +keyword|defun& @foo (#1) {Hello, #1!}
594 #at_off
595 -%}
596 One can not using \builtin|at_off|, but I strongly recommend to match

```

```

597 pairs.
598
599 \subsection{\buitin|ltx3_on| and \buitin|ltx3_off| builtins}
600 Those builtins are similar with \buitin|at_on| and \buitin|at_off|
601 pairs but for \LaTeX3.
602
603 \subsection{\buitin|textmode| and \buitin|mathmode| builtins}
604 Internally, vesti tracks so called {\tt text mode} and {\tt math mode}.
605 In the math mode, for instance, the token \verb|>| is changed into $->$ inside
606 of the math mode. The idea is that Vesti changes \verb|>| into \verb|\to|, and
607 so on. But when defining some function using \defun*, for example, one might
608 want to define
609 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
610 +keyword|useenv@ foo {-><-}
611 -%}
612 so that \verb|$ \foo$| makes $-><-$, one should change the mode. Here,
613 \buitin|mathmode| comes into the place. One should write instead that
614 useenv Verbatim [numbers=left, numbersep=5pt, frame=single, commandchars=+|@]{%-
615 +keyword|useenv@ foo {#mathmode{-><-}}
616 -%}
617
618 \section{Lua API}
619 Vesti uses Lua in both building script and inline inside of Vesti code.
620 Below are functions which are baked in Vesti compiler.
621 useenv table [ht] {
622     \centering
623     #::
624     local content = read_all("../src/Lua.zig")
625
626     local pat = '%.name%s*=%s*"'([~"]+)"'
627
628     local lua = {}
629     for name, tok in content:gmatch(pat) do
630         lua[#lua + 1] = name
631     end
632     table.sort(lua)
633
634     vesti.print([[ \begin{tabular}{ccccc} ]])
635
636     for i, kw in ipairs(lua) do
637         local cell = string.format("\ttt{%s}", kw)
638         if (i % 4) == 0 then
639             vesti.print(cell .. [[\]])
640         else
641             vesti.print(cell .. "&")
642         end
643     end
644
645     vesti.print([[ \end{tabular} ]])
